## Chemometrics for Spectroscopists

Intensive Course Kraków  
2021-11-29 – 12-03

Claudia Beleites  
Chemometric Consulting Claudia Beleites

# What is Chemometrics?

## Definition

Chemometrics means applying statistics (mathematics) to solve chemical problems:

- Design of Experiments (DoE)
- Data analysis
- Quantitative Structure-Activity Relations (QSAR)

Very similar disciplines (statistics for other sciences):

- Biometrics
- Psychometrics
- ...

## Introduction to Chemometrics

C. Beleites

### Introduction

Spectra are high dimensional data  
High dimensional data

Curse of Dimensionality  
No Free Lunch Theorem

Data Analysis  
Bilinear Models

Summary

# Why bother about statistics?

- Data and/or problem is too complex for “simple” analysis:
  - too many factors influencing the problem  
many sources of variance
  - information is spread out over many variables;  
no single variable carries enough information
  - information is hidden between lots of noise
- even a univariate linear calibration is chemometrics
- practical considerations
  - extract information with lowest possible number of experiments
  - “rescue” experiments that could not be performed according to sampling plan
  - good practice for data analysis

# Analytical Process

### Introduction

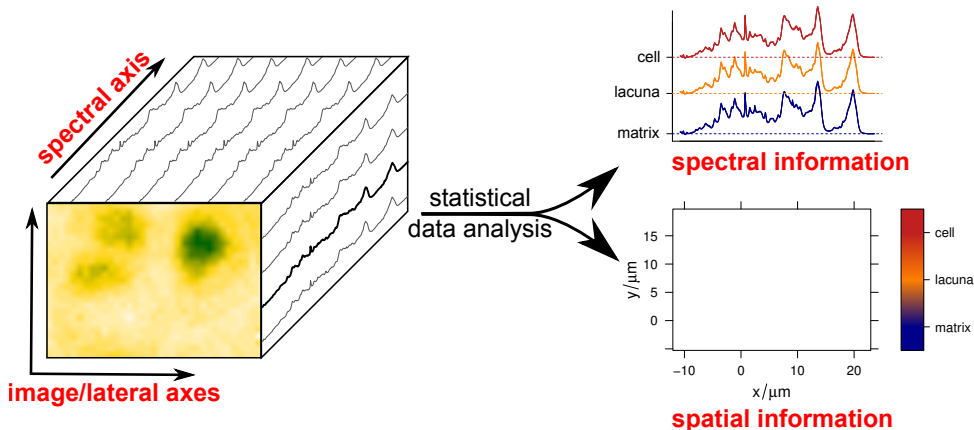

Spectra are high dimensional data  
High dimensional data  
Curse of Dimensionality  
No Free Lunch Theorem

Data Analysis  
Bilinear Models

Summary

- 1 Design of experiment  
sampling theory
- 2 Measurements
- 3 Modeling
  - choice of model type
  - pre-processing
  - choice of model hyper-parameters
  - model fitting
- 4 Interpretation of the model
- 5 Validation: Assessment of model quality
- 6 Use the model

# Hyperspectral Data

- imaging data acquired with high spectral resolution
- $p$  spectral bands (wavelengths, wavenumbers, frequencies)
- image domain:  $n = n_x \times n_y$  pixels
- analyse image and/or spectral domain

# Curse of Dimensionality

Chemometric Models are functions in  $p$ -dimensional space.

(Un)certainty depends on:

- noise (signal-to-noise ratio) of measurement/input variates
- degrees of freedom (no. of parameters) of the model
- sampling density

# Curse of Dimensionality

Chemometric Models are functions in  $p$ -dimensional space.

(Un)certainty depends on:

- noise (signal-to-noise ratio) of measurement/input variates
- degrees of freedom (no. of parameters) of the model
- sampling density

# Curse of Dimensionality

Chemometric Models are functions in  $p$ -dimensional space.

(Un)certainty depends on:

- noise (signal-to-noise ratio) of measurement/input variates
- degrees of freedom (no. of parameters) of the model
- sampling density

constant sample density:  $n \sim \left(\frac{1}{\text{density}}\right)^p$  exponential with  $p$

High dimensional data

Curse of Dimensionality  
No Free Lunch Theorem

Data Analysis  
Bilinear Models

Summary

# Curse of Dimensionality

Need exponentially increasing sample number with growing  $p$ !

# Recommended sample size

- in general (i.e. non-linear model):  $n \sim \left(\frac{1}{density}\right)^p$
  - univariate linear regression: 10 samples
  - multivariate linear model: 3 – 5 independent samples / input variate
  - linear classifiers:  $5p$  independent samples / class  
IR spectrum 600 – 1800  $\text{cm}^{-1}$ :  
 $p = 601$  data points  $\Rightarrow$  3005 samples (patients) / class
  - How complex a model can we afford?
- $\rightsquigarrow$  Always measure stability of the model.

**Analogy:** Think of chemometric model like an analytical instrument, or the part of an instrument.

Random Error  
Variance type Uncertainty  
low Precision

Systematic Error  
Bias type Uncertainty  
low Accuracy

- Spectra are subject to bias & variance
- Models are subject to bias & variance
- Predictions are subject to bias & variance

## No Free Lunch in Search and Optimization

No classification method is better than any other compared across all possible problems.

For each problem that is efficiently optimized by a given heuristic, many related functions can be derived where the heuristic is bad.

- Search space = model complexity: spectra space + hyperparameters
- ↪ Data-driven optimization is expensive in sample size
- **Consequence:** Method needs to be adapted to problem
- External knowledge makes modeling successful
  - Domain knowledge about application/task/problem  
biological, chemical, physical, spectroscopic, ...
  - Domain knowledge about data analysis  
judge model complexity, sample size requirements, experimental plans, ...

### Introduction

Spectra are high dimensional data  
High dimensional data  
Curse of Dimensionality  
No Free Lunch Theorem

Data Analysis  
Bilinear Models

Summary

# Qualitative vs. Quantitative

**Qualitative Analysis** answers a yes/no question.

- Is there any  $x$  in my sample?
- Does the sample express a certain property?
- Does the sample belong to a certain class/group of samples?

e.g. Classification

Cluster Analysis

**Quantitative Analysis** quantitates properties

- How much  $x$  is in my sample?

e.g. Regression

# Prediction vs. Description

**Predictive** methods are used to build models that predict certain properties for new data.

**Descriptive** models are used to explain a problem, its influencing factors, and so on.

- Predictive models can also be used for description.
- Predictive models are always supervised.

# Supervised vs. Unsupervised

**Supervised methods** have a *dependent* variable and use additional information about the particular property of interest.

Models are built using examples with known outcome.

**Unsupervised methods** do not use additional information.

Models are built without any known true outcome.

# Parametric vs. Non-Parametric

**Parametric** models assume a particular distribution for the variates

e.g. Confidence interval calculation using  $x = \bar{x} \pm t(1 - \frac{\alpha}{2}; n - 1)s$   
LDA: Multivariate Gaussian with equal COV for all classes

**Non-Parametric** models do not need any particular distribution

e.g. Confidence interval calculation using bootstrap  
prediction interval using percentiles of test sample predictions  
*k*-nearest Neighbour Classification

Introduction

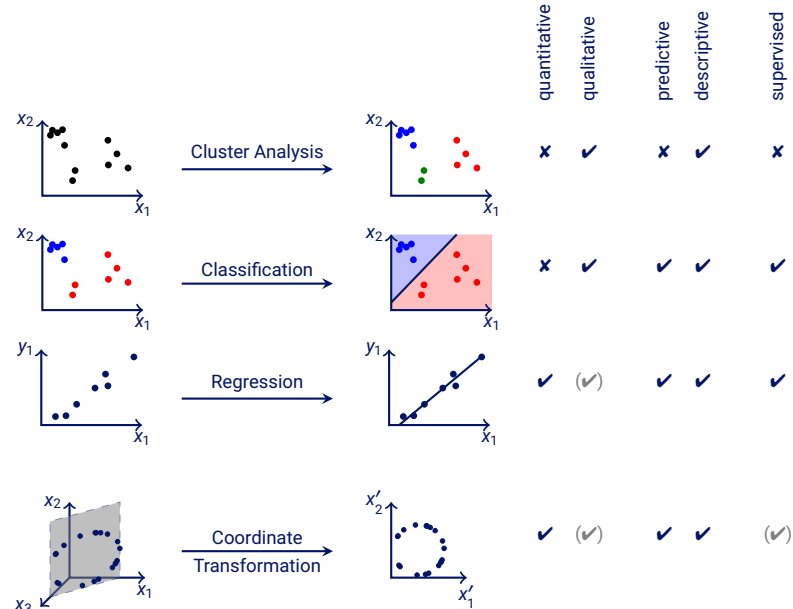

Spectra are high dimensional data  
High dimensional data  
Curse of Dimensionality  
No Free Lunch Theorem

Data Analysis  
Bilinear Models

Summary

# Hard vs. Soft models

- **Hard models** are based on physical, chemical, physico-chemical, biological model  
e.g. fit reaction kinetics of pre-specified order with given pure-component spectra
- work well if assumptions met,
- but can fail badly if assumptions are violated
- **Soft models** do not use such an application background  
e.g. PLS regression
- application background enters via model interpretation
- less dependent on assumptions
- typically more uncertainty
- no sharp boundary: e.g. MCR-ALS

Bilinear Models

Summary

# Bilinear Models

$$\mathbf{X}^{(n \times p)} = \mathbf{C}^{(n \times m)} \mathbf{S}^{(m \times p)}$$

The diagram illustrates the bilinear model equation  $\mathbf{X}^{(n \times p)} = \mathbf{C}^{(n \times m)} \mathbf{S}^{(m \times p)}$ . The matrix  $\mathbf{X}$  is shown as a vertical stack of five spectra (rows) with varying peak positions and widths. The matrix  $\mathbf{C}$  is a 5x2 matrix of component loadings, with values:  $\begin{bmatrix} 0.33 & 0.00 \\ 1.00 & 0.00 \\ 0.00 & 0.33 \\ 0.33 & 0.33 \\ 0.33 & 0.67 \\ 0.00 & 1.00 \end{bmatrix}$ . The matrix  $\mathbf{S}$  is shown as a vertical stack of two spectra (rows) representing the pure components.

Spectra are high dimensional data  
High dimensional data

Curse of Dimensionality  
No Free Lunch Theorem

Data Analysis  
Bilinear Models

Summary

# Summary

---

- Spectra matrix + meta-data
- Spectra as points in high-dimensional space:  
Beware of curse of dimensionality
- No free lunch: data-driven optimization is costly  
Use external knowledge
- Method classes: Cluster analysis, Classification, Regression, ...
- Bilinear models: strong physical background (linear spectroscopy)
- Bias- & variance-type uncertainty lurk everywhere
- Chemometrics on whole spectra: Variance is the danger  
Easy to overlook, often the main contributor to the total error
- Chemometrics on few wavelengths: much better situation  
Elephant in the room: wavelength selection
